In the ground state of the doped two-leg Hubbard ladder there are power-law decaying $d_{x^2−y^2}$-type pairing correlations. It is important to know the strength and the temperature scale of these correlations. For this purpose, we have performed determinantal Quantum Monte Carlo (QMC) calculations of the reducible particle-particle interaction in the Hubbard ladder. In this paper, we report on these calculations and show that, at sufficiently low temperatures, resonant particle-particle scattering takes place in the $d_{x^2−y^2}$ pairing channel for certain values of the model parameters. The QMC data presented here indicate that the $d_{x^2−y^2}$ pairing correlations are strong in the Hubbard ladder.

It is generally accepted that the high-$T_c$ cuprates [1] are $d_{x^2−y^2}$-wave superconductors [2, 3]. It is also known that the spin-fluctuation exchange in electronic models [4, 5] and an electron-phonon interaction which has its largest coupling at small wavevectors [6–8] can lead to an effective electron-electron interaction which is attractive in the $d$-wave Bardeen-Cooper-Schrieffer (BCS) pairing channel. However, it is not yet clear what is the pairing interaction responsible for superconductivity in the high-$T_c$ cuprates. Within this context, it is important to determine the maximum possible strength of the $d_{x^2−y^2}$ pairing correlations which one can obtain in a purely electronic model such as the Hubbard model. Unfortunately, the ground state of the two-dimensional (2D) Hubbard model remains beyond the reach of the exact many-body techniques [9]. However, in the case of the two-leg Hubbard ladder, the Density Matrix Renormalization Group (DMRG) calculations found power-law decaying $d_{x^2−y^2}$-type pair-field correlations [10, 11]. This is probably the only model where it is known from exact calculations that the pairing correlations get enhanced by turning on an onsite Coulomb repulsion in the ground state [11, 12]. Hence, it is important to determine the maximum possible strength and the temperature scale of the $d_{x^2−y^2}$ pairing correlations in the Hubbard ladder, which is the main motivation of this paper.

Here, we present Quantum Monte Carlo (QMC) results on the reducible particle-particle interaction $\Gamma$ in the BCS channel, which is illustrated in Fig. 1. The reducible $\Gamma$ serves as a powerful probe of the pairing correlations. For example, in the case of an s-wave superconductor, $\Gamma$ at the Fermi surface would diverge to $−\infty$ due to repeated particle-particle scatterings in the BCS channel, when the superconducting transition is approached, $T \to T_c^+$. In this paper, we investigate the strength of the $d_{x^2−y^2}$ pairing in the Hubbard ladder by making use of the exact QMC data on $\Gamma$.

In the following, we show that the reducible particle-particle interaction $\Gamma$ in the Hubbard ladder exhibits diverging behavior as the temperature is lowered for certain values of the model parameters. We find that, on the Fermi surface, $\Gamma$ can become strongly repulsive (attractive) for $q \approx (\pi, \pi)$ ($q \approx 0$) momentum transfers, which correspond to backward (forward) scatterings. In particular, near half-filling and for Coulomb repulsion $U = 4t$ and temperature $T = 0.1t$, where $t$ is the hopping matrix element, the backward and forward scattering amplitudes can become an order of magnitude larger than the bare Coulomb repulsion or the bare bandwidth. This type of momentum dependence of $\Gamma$ implies that resonant particle-particle scattering is taking place in the BCS channel already at $T \approx 0.1t$. For $U = 8t$, we observe similar behavior at about twice higher temperatures. The temperatures studied in this paper are lower than those reached in previous QMC calculations of $\Gamma$ for the 2D [13] and the two-leg [14] Hubbard models. In addition, we present results on the solution of the Bethe-Salpeter equation in the BCS channel, which quantitatively determines the strength of the pairing correlations. The QMC data shown in this paper imply that the $d_{x^2−y^2}$-type pairing in the two-leg Hubbard ladder is strong for certain values of the model parameters.

We begin by briefly describing the previous studies of $d_{x^2−y^2}$ pairing in the Hubbard ladder. The DMRG calculations found that the rung-rung pair-field correlation function decays as power law in the ground state of the

---

**FIG. 1:** Feynman diagram for the reducible particle-particle interaction $\Gamma(p'|p)$ in the BCS channel. Here, $p$ denotes $(p, \omega_n)$ with Matsubara frequency $\omega_n$. In this diagram, the incoming fermions at states $p$ with up spin and $−p$ with down spin scatter to states $p'$ with up spin and $−p'$ with down spin by exchanging $q = p' − p$. The bare Coulomb repulsion or the bare bandwidth. This type of momentum dependence of $\Gamma$ implies that resonant particle-particle scattering is taking place in the BCS channel already at $T \approx 0.1t$. For $U = 8t$, we observe similar behavior at about twice higher temperatures.
chain hopping pairing correlations are most enhanced when the inter-
doped Hubbard ladder \[10\]. The mean-field calculations
suggested the \(d_{x^2−y^2}\) type of symmetry for pairing in
doped spin ladders \[15\]. The exact-diagonalization \[12\] and
the DMRG \[11\] calculations found that the \(d_{x^2−y^2}\) pairing correlations are most enhanced when the inter-
chain hopping \(t_\perp\) is greater than the intrachain hopping \(t\), in particular, for \(t_\perp ≈ 1.5t\) in the intermediate cou-
pling regime and near half-filling. In this case, the QMC calculations showed that the irreducible particle-particle
interaction peaks for momentum transfers near \((\pi, \pi)\) due
to antiferromagnetic fluctuations \[14\].

The two-leg Hubbard model is defined by

\[
H = -t \sum_{i,\lambda,\sigma} (c_{i,\lambda,\sigma}^\dagger c_{i+1,\lambda,\sigma} + \text{h.c.}) - t_\perp \sum_{i,\sigma} (c_{i,1,\sigma}^\dagger c_{i,2,\sigma} + \text{h.c.}) + U \sum_{i,\lambda} n_{i,\lambda,\uparrow} n_{i,\lambda,\downarrow} - \mu \sum_{i,\lambda,\sigma} n_{i,\lambda,\sigma},
\]

where \(t\) is the hopping parameter parallel to the chains
(along \(\hat{x}\)), and \(t_\perp\) is for hopping perpendicular to the
chains (along \(\hat{y}\)). The operator \(c_{i,\lambda,\sigma}^\dagger (c_{i,\lambda,\sigma}\) creates (an-
nihilates) an electron of spin \(\sigma\) at site \(i\) of chain \(\lambda\), and
\(n_{i,\lambda,\lambda'} c_{i,\lambda,\sigma}\) is the electron occupation number.
As usual, \(U\) is the onsite Coulomb repulsion, and \(\mu\) is the
chemical potential. In addition, periodic boundary
conditions were used along the chains, and \(t_\perp\) denotes
interchain hopping for open boundary conditions.

In obtaining the data presented here, the determinan-
tal QMC technique described in Ref. [16] was used.
The calculation of the reducible interaction \(\Gamma\) follows the pro-
cedure described in Ref. [13] for the 2D case. The BCS
component of the reducible particle-particle interaction
\(\Gamma(p'|p)\) is illustrated in Fig. 1, where \(p = (p, i\omega_n)\) with
Matsubara frequency \(\omega_n = (2n + 1)\pi T\). In the following,
results will be shown for the reducible interaction in the
singlet channel, \(\Gamma_s(p'|p) = \frac{1}{2} [\Gamma(p'|p) + \Gamma(-p'|p)]\). In par-
cular, the momentum dependence of \(\Gamma_s(p, i\omega_n|p, i\omega_n)\)
will be shown at the lowest Matsubara frequency \(\omega_n =
ω_n' = πT\). In the ground state and for \(U = 4t\), the
d\(d_{x^2−y^2}\)-type pairing correlations are most enhanced near
half-filling for \(t_\perp ≈ 1.6t\) \[11\]. When \(U = 8t\), this
occurs for \(t_\perp ≈ 1.4t\). In this paper, the QMC data will
be presented using these two parameter sets for a \(2 \times 16\)
lattice.

The momentum structure in \(\Gamma_s(p'|p)\) depends sensi-
tively on where \(p'\) and \(p\) are located with respect to the
Fermi surface. Hence, we will first show results on the
single-particle spectral weight \(A(p, \omega) = -\frac{1}{\pi} \text{Im} G(p, \omega +
iδ)\), where \(G\) is the single-particle Green’s function, and
discuss the location of the Fermi-surface crossing points.
We have obtained \(A(p, \omega)\) from the QMC data on the
single-particle Green’s function along the Matsubara-
time axis by using the maximum-entropy analytic con-
 tinuation method. Figure 2 shows \(A(p, \omega)\) versus \(\omega\) for
\(T = 0.1t, U = 4t, t_\perp = 1.6t\) and \((\eta) = 0.94\). Here,
we see that the Fermi level crossing for the antibond-
ing \((p_y = π)\) band occurs for \(p_x\) between \(π/8\) and \(π/4\),
while for the bonding \((p_y = 0)\) band there is spectral
weight pinned near the Fermi level for \(3π/4 ≤ p_x ≤ π\)
at this temperature. These results for \(A(p, \omega)\) are sim-
ilar to those presented in Refs. \[11, 14\]. In the follow-
 ing, \(\Gamma_s(p', iπT|p, iπT)\) versus \(p\) will be shown for
\(p' = (π/4, π)\) near the Fermi level and for \(p' = (0, π)\)
at the saddle point.

Figure 3(a) shows \(\Gamma_s(p', iπT|p, iπT)\) versus \(p\) while \(p'\)
is kept fixed at \((π/4, π)\). In the left panel, \(p_x\) is scanned
from \(−π\) to \(π\) for \(p_y = 0\), while in the right panel \(p_x\) is
scanned for \(p_y = π\). Here, it is seen that repul-
sive and attractive peaks develop in \(\Gamma_s\), as \(T\) decreases
from 0.25\(t\) to 0.1\(t\). In particular, in the left panel it is seen
that, when \(p ≈ (−3\pi/4, 0)\), a repulsive peak de-
velops in \(\Gamma_s\), which corresponds to a scattering process
with momentum transfer \(q ≈ (π, π)\). In addition, in the
right panel it is observed that a dip develops in \(\Gamma_s\) when
\(p ≈ p' = (π/4, π)\) corresponding to zero momentum
transfer. This dip is due to resonant scattering in the
d\(d_{x^2−y^2}\)-wave BCS channel. In a three-dimensional infinite
system, when a \(d_{x^2−y^2}\)-wave superconducting instability is
approached, \(\Gamma_s(p', iπT|p, iπT)\) at the Fermi level diverges
to \(+\infty\) for backward scattering, and to \(−\infty\) for
forward scattering, which will be further discussed below.
In Fig. 3(a), it is seen that \(\Gamma_s\) is developing this type of
repulsive and attractive peaks at \(T\) of order 0.1\(t\).

Figure 3(b) shows \(\Gamma_s(p', iπT|p, iπT)\) versus \(p\) while \(p'\)
is kept fixed at the saddle point \((0, π)\). In this case, \(\Gamma_s\)
develops a peak when $p = (\pm \pi, 0)$, corresponding to scattering with $q = (\pi, \pi)$ momentum transfer. The magnitude of this peak is comparable to that seen in the left panel of Fig. 3(a). However, the behavior for $q = 0$ momentum transfer is different. As observed in the right panel of Fig. 3(b), $\Gamma_\alpha$ for $q = 0$ scattering remains pinned near zero for $T$ down to 0.125$t$, and becomes attractive only below this temperature. Hence, at the saddle point $(0, \pi)$, the resonant scattering in $\Gamma_\alpha$ for $q = 0$ momentum transfer is weaker compared to that at $(\pi/4, \pi)$.

Figure 4 shows the $T$ dependence of the backward and forward scattering components of $\Gamma_\alpha$. Here, $\Gamma_\alpha$ is plotted as a function of the inverse temperature $\beta$ for momentum transfers $q = (\pi, \pi)$ and $(\pi/8, 0)$, while $p'$ is kept fixed at $(\pi/4, \pi)$. This figure shows that, near the Fermi level, the backward and forward scattering amplitudes increase rapidly at low $T$, becoming an order of magnitude larger than the bare Coulomb repulsion at $T \approx 0.1t$.

Figures 3 and 4 display the main features of $\Gamma_\alpha$, which can be summarized as follows: At low $T$, there are strong $q \approx (\pi, \pi)$ scatterings over the whole Brillouin zone, while the $q \approx 0$ scatterings are most attractive near the Fermi surface. These features were observed at $\langle n \rangle = 0.94$ and 0.875, and for $U = 4t$ and 8$t$. The one-loop Renormalization-Group (RG) technique is also utilized to obtain the momentum dependence of $\Gamma$ in the Hubbard model [17, 18]. It would be useful to compare $\Gamma$s with those in the paper.

\[
\lambda_\alpha = \frac{T}{2 N} \sum_p |p| G(p') |\phi_\alpha(p')|^2 \phi_\alpha(p'),
\]

was solved for $\lambda_\alpha$ and the corresponding eigenfunctions $\phi_\alpha(p, i\omega_n)$ by using QMC data on $\Gamma$ and the single-particle Green's function $G(p)$. For a three-dimensional infinite system, when the maximum $\lambda_\alpha$ reaches 1, this signals a BCS instability to a state where the pair wave function has the form of the corresponding eigenfunction. For a one-dimensional system, $\lambda_\alpha$'s will always be less than 1, however, the $T$ dependence of $\lambda_\alpha$'s gives information about the characteristic temperature scale of the pairing correlations. For instance, if the maximum eigenvalue reaches 0.9 at some temperature, then this means that the leading pairing correlations are enhanced by a factor of 10 through repeated particle-particle scatterings in the BCS channel. Hence, at this temperature, the system would exhibit strong pairing fluctuations.

At low temperatures, the maximum $\lambda_\alpha$ of the Bethe-Salpeter equation corresponds to an eigenfunction $\phi_{d}(p, i\omega_n)$ which has $d_{x^2-y^2}$ type of symmetry in the sense that it changes sign as $p$ goes from $(\pi, 0)$ to $(0, \pi)$ in the Brillouin zone [14]. The temperature evolution of the $d_{x^2-y^2}$-wave irreducible eigenvalue $\lambda_d$ is shown in Figure 5(a) for $U = 4t$ and $t_\perp = 1.6t$. As $T$ decreases, $\lambda_d$ grows monotonically reaching 0.75 at $T = 0.1t$ for $\langle n \rangle = 0.94$. The simple extrapolation of these results suggests that $\lambda_d$ will reach 0.9 at $T > 0.06t$ for $\langle n \rangle = 0.94$. At the temperatures where these calculations were performed,
λ_d decreases upon doping to ⟨n⟩ = 0.875. Because of the QMC “fermion sign problem” [19], these data were obtained by using parallel computers. Also shown in Fig. 5(b) is λ_d for U = 8t and t⊥ = 1.4t. We find that, at T ≥ 0.25t, λ_d takes larger values for U = 8t than for U = 4t. These results indicate that the d_x^2−y^2 pairing correlations are strong in the Hubbard ladder.

An important feature of the QMC data presented here is that, at sufficiently low T, Γ_s near the Fermi level becomes strongly attractive for q ≈ 0 momentum transfers. This is due to resonant scattering in the d_x^2−y^2-wave BCS channel. In order to demonstrate this effect, consider the case of an irreducible interaction Γ_1 which is independent of frequency and separable in momentum,

$$\Gamma_1(p'|p) = \sum_\alpha V_\alpha g_\alpha(p')g_\alpha(p)$$  \hspace{1cm} (3)

where α denotes the various pairing channels. In this case, the reducible interaction is given by

$$\Gamma(p'|p) = \sum_\alpha \frac{V_\alpha}{1 - V_\alpha P_\alpha^2} g_\alpha(p')g_\alpha(p),$$ \hspace{1cm} (4)

where $$P_\alpha = -(T/N)\sum_p g^2_\alpha(p)|G(p)|^2$$ and $$V_\alpha = \frac{1}{2}(\cos px - \cos py)$$. In general, Γ_1 has both attractive and repulsive V_α. In Eq. (4), it is seen that the repulsive components get suppressed by repeated scatterings in the BCS channel, while the attractive components get enhanced. For the d_x^2−y^2 channel, g_α(p) = \frac{1}{2}(\cos px - \cos py). If the d_x^2−y^2 component of Γ_1 is attractive and gets sufficiently enhanced, here it is observed that Γ for q = p' − p ≈ 0 can become attractive. When a d_x^2−y^2-wave BCS instability is approached, then, at the Fermi surface, Γ_1 diverges to −∞ for q ≈ 0 scatterings and to +∞ for q ≈ (π, π) scatterings. The important point is that the exact QMC data for Γ_s also exhibit this type of momentum dependence in the Hubbard ladder at temperatures which are not low.

In summary, we have presented QMC data on the reducible particle-particle interaction Γ_s in order to determine the strength and the temperature scale of the d_x^2−y^2 pairing correlations in the two-leg Hubbard ladder. We found that Γ_s displays diverging behavior as the temperature decreases. In particular, Γ_s exhibits resonant scattering in the d_x^2−y^2 pairing channel as it would be expected for a system near a d_x^2−y^2 BCS instability. We have also shown results on the solution of the Bethe-Salpeter equation to quantitatively determine the strength of the d_x^2−y^2 pairing. The QMC data presented in this paper indicate that the d_x^2−y^2 pairing correlations in the Hubbard ladder are strong for certain values of the model parameters. We note that, for comparison, it would be useful to investigate the strength of d_x^2−y^2 pairing for a two-leg ladder system which includes both onsite Coulomb and electron-phonon interactions.
